

# NEXT GENERATION ANODES FOR LITHIUM-ION BATTERIES: OVERVIEW

**DENNIS DEES**

2016 U.S. DOE HYDROGEN and FUEL CELLS  
PROGRAM and VEHICLE TECHNOLOGIES  
OFFICE ANNUAL MERIT REVIEW AND PEER  
EVALUATION MEETING

**Project ID ES261**

# OVERVIEW

## Timeline

- Start: October 1, 2015
  - Kickoff: January, 2016
- End: September 30, 2018
- Percent Complete: 17%

## Budget

- Total project funding:
  - FY16 - \$4000K
- ES261 and ES262

## Barriers

- Development of PHEV and EV batteries that meet or exceed DOE and USABC goals
  - Cost, Performance, and Safety

## Partners

- Sandia National Laboratories
- Oak Ridge National Laboratory
- National Renewable Energy Laboratory
- Lawrence Berkeley National Laboratory
- Argonne National Laboratory

# RELEVANCE

## Battery Performance and Cost (BatPaC) Model Utilized to Establish Relevance by Connecting Pack to Anode Targets

- Pack level benefits reach diminishing returns after **1000 mAh/cm<sup>3</sup>** for both cost and energy density
  - $\text{mAh/cm}^3 [\text{electrode basis}] = \rho \cdot \varepsilon \cdot Q [ \text{g/cm}^3_{\text{act}} \cdot \text{cm}^3_{\text{act}} / \text{cm}^3_{\text{elect}} \cdot \text{mAh/g} ]$
- Silicon with <75 wt% graphite can achieve target

45 kWh<sub>use</sub>, 90 kW 360 V  
\$20/kg 200 mAh/g NMC cathode

Wh/L  
including  
foam between  
cells 2x  
volume  
expansion

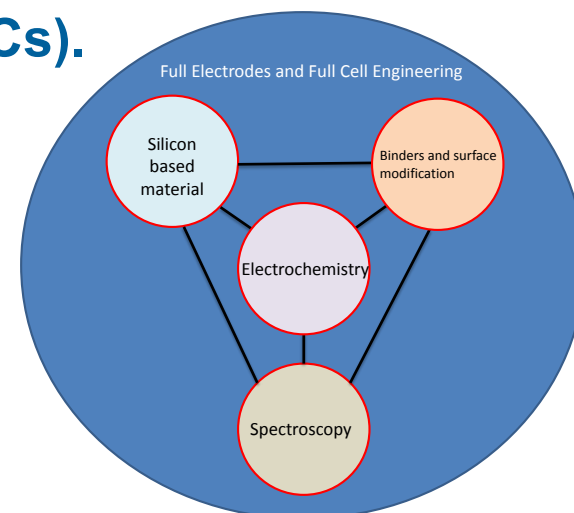

Electrode volumetric capacity uses lithiated basis  $\text{Li}_{4.4}\text{Si}$  or  $\text{Li}_{4.4}\text{Sn}$  and maximum active material volume fraction of 65%

# APPROACH

## Initial Focus on Insights into and Advancement of Silicon-Based Materials, Electrodes, and Cells (SiBMECs).

- Stand-up program, based on expertise and past work:
  - Develop technical targets
  - Assign individual responsibilities
  - Initiate work
  - Establish communications
- Anode advancements verified based on life and performance of full cells.
  - Establish baseline SiBMECs and testing protocols.
  - Supported by Cell Analysis, Modeling, and Prototyping (CAMP) facility and Battery Manufacturing Facility (BMF)
- Plan and conduct a wide range of diagnostic studies on SiBMECs.
  - Establish structure-composition-property relationships.
  - Lithium-alloying surface and bulk transport and kinetic phenomena.
  - Assessment of failure modes.
  - Supported by Post-Test Facility (PTF)
- Evaluation of safety and abuse tolerance of SiBMECs.
  - Supported by Battery Abuse Testing Laboratory (BATLab)

# APPROACH (CONTINUED)

## As the Program Matures, Materials Developments will be Incorporated into Baseline SiBMECs.

- Materials development on SiBMECs to enhance interfacial stability, accommodate intermetallic volume changes, and improve overall performance and life.
  - Explore lithium inventory strategies.
  - Study alternative high-energy metals:  $\text{Me}_x\text{Si}_{0.66}\text{Sn}_{0.34}$  (Me: Cu, Ni, Fe, Mn).
  - Examine a wide range of functional binders.
  - Interfacial modifications: MLD/ALD, surface coatings, and electrolyte additives.
- Materials advances can be scaled-up with the support of the Materials Engineering Research Facility (MERF).
- Materials advances will be incorporated into baseline SiBMECs with support of BMF and CAMP facility.
- Communicate progress to battery community.
  - Open to industrial participation and/or collaboration that does not limit program innovation or the free flow of information

# ADOPTED ELECTRODES AND PROTOCOLS FROM CAMP FOR INITIAL BASELINES

## Full Baseline Cells Capacity Fade

# SILICON CONTENT HAS SIGNIFICANT IMPACT ON VOLTAGE PROFILE AND CURRENT EFFICIENCY

## Full Baseline Cells Current Efficiency

- Strong correlation between plateaus in SiGr and Gr
- $\text{Li}_{15}\text{Si}_4$  presence in cells discharged below 50 mV

**As the Silicon content increases:**

- Specific energy increases
- Increased voltage hysteresis
- Lower current efficiency

## Half-Cells Voltage Profile

# ELECTROCHEMICAL INVESTIGATIONS INCLUDE REFERENCE ELECTRODE STUDIES

Baseline NCM523/SiGr, Li RE, ~C/30, 2.5-4.3 & 3-4.1 V voltage windows

For cells discharged to 2.5 V, 10% of capacity is between 3 & 2.5 V. However, at a cell voltage of 2.5 V, the negative electrode potential is 1.12 V, which increases the likelihood of SEI decomposition and gas generation. Limiting LCV to 3.0 V improves cell life.

# USING NMR SPECTROSCOPY TO STUDY SILICON AND INTERMETALLIC ELECTRODES

## *ex-situ* Multinuclear MAS NMR, *in-situ* NMR and Solutions NMR

- $^7\text{Li}$  and  $^{29}\text{Si}$  NMR have been used to reveal entire Li-Si reaction mechanism
- $^7\text{Li}$ - $^{29}\text{Si}$ - $^1\text{H}$ - $^{19}\text{F}$ - $^{13}\text{C}$  MAS NMR correlation experiments have been used to understand SEI formation, nature of degradation products and other reactions in a silicon based electrode.
- It is possible to effectively study anode SEI and amorphous  $\text{Li}_x\text{Si}$  composition both qualitatively and quantitative via NMR studies on silicon and other intermetallics electrodes

# DIAGNOSTIC STUDIES OF MODEL SILICON-BASED ANODES

ES262

Characterization Studies on Thin Film Si, Si/C, and Si/Binder Electrodes; also Silicon Nano-Wire Electrodes

Schematic diagram of the experimental arrangement for EQCM-D measurements

- Apply electrochemical, *ex-situ* and *in-situ* optical, X-ray, and neutron probes capable of sensing surface layers at a submonolayer sensitivity and resolution
- Study *in situ* surface mass changes of electrodes during electrochemical processes

# EVALUATION OF SAFETY AND ABUSE TOLERANCE OF SILICON ELECTRODES

## Initiated Studies on Electrodes and Cells

- The reactivity with silicon-based anodes under abuse is largely unknown.
- Key issues related to safety include understanding of energetics during thermal runaway, reactivity with electrolytes, abuse tolerance at the cell level, and gas decomposition products generated at these electrodes.
- Previous limited studies on low silicon content (~5%) electrodes clearly indicate the increased heat and gas generation with silicon cells.
- Electrochemical performance of 15% silicon electrodes made to baseline specifications in good agreement to CAMP electrodes.
- Thermodynamic evaluations are ongoing.

Thermal runaway enthalpy of NMC/Si-C cells is ~10% greater than NMC/Graphite cells

Difference in gas generation attributed to the differences in surface reactivity and surface products generated at the anode/electrolyte interface

# ADDING LITHIUM INVENTORY TO COUNTER COULOMBIC EFFICIENCY LOSSES

Initial approach using  $\text{Li}_5\text{FeO}_4$  (LFO) (theoretical 867, actual ~760 mAh/g) as a sacrificial cathode additive

- Sacrificial lithium source additive in positive electrode being implemented.
- Modeling being utilized to predict impact.
- Synthesized new batch of LFO for blending with baseline NMC cathode.
- Other alternatives being considered.
  - Investigate sacrificial lithium species additive introduced via electrolyte
  - Use chemistry to pre-lithiate Si powders or electrodes; test and conduct feedback

# DEVELOPMENT OF HIGH ENERGY METALS

## Initial Studies on Amorphous $\text{Si}_{0.64}\text{Sn}_{0.36}$

*Journal of The Electrochemical Society*, 150 (2) A149-A156 (2003)

*J. Phys. D: Appl. Phys.* 47 (2014) 393001

- Amorphous  $\text{Si}_{0.64}\text{Sn}_{0.36}$  thin film exhibits high discharge capacity ( $>2000$  mAh/g) and low irreversible capacity ( $\sim 100$  mAh/g).
- Immiscible gap between Si and Sn, and low melting T of Sn ( $232^\circ\text{C}$ ) appear to be the main challenge for  $\text{Si}_{0.64}\text{Sn}_{0.36}$  large-scale synthesis.

# FUNCTIONAL POLYMER BINDER DEVELOPMENT FOR SILICON BASED ELECTRODES

**Ideal binders should have excellent chemical stability; exceptional mechanical, flexibility, and adhesive properties; as well as high ionic and electronic conductivity. THERE ARE NO IDEAL BINDERS.**

- Polypyrene (PPy)-based polymers are being studied as functional conductive binders
- Linear siloxanes have many desirable properties such as elasticity and durability but lack adhesion and conductivity. Incorporation of cross-linking network would improve the tensile strength and adhesive properties.

- Introduction of electron rich pendants would improve the conductivity.

# FUNCTIONAL POLYMER BINDER DEVELOPMENT FOR SILICON BASED ELECTRODES

## Continued

- A variety of functional polymers are being explored that have desirable characteristics including strong adhesion, ionic conduction and electronic conduction. Examples: Polycarbonate-based polymer binders and Single-ion (Li) conducting polymer binders.

R: (1)

- Acrylate-based, comb- and brush-copolymers bearing hydrogen bond donors and hydrogen bond acceptors in the side chains will afford a flexible, dynamic secondary structure which will adapt to the dynamic size and shape of the anode particles, much like a net surrounding fruit.

hydrogen bond donor and acceptor sites

$R^1, R^2 = \text{H, Alk, Ar, N-het, O-het, CONR}_2, \text{NR}^3\text{R}^4$

$R^3, R^4 = \text{H, Alk, COAlk, COAr, CONR}_2$

# SURFACE MODIFICATION USING MOLECULAR AND ATOMIC LAYER DEPOSITION (MLD & ALD)

Initial MLD studies focus on aluminum-glycerol (AIGL) alkoxide ultrathin films from trimethylaluminum and glycerol precursors.

- Advantages of MLD/ALD coatings include conformal and atomic thickness control, especially powerful for 3-D nano complex architectures such as electrodes, and commercially scalable process.
- Developed MLD alkoxide coatings for both silicon nanoparticles and baseline silicon anodes.
- Initial electrochemical studies of coated particles and electrodes in half-cells are promising.

# SURFACE MODIFICATION USING PARTICLE COATINGS AND ELECTROLYTE ADDITIVES

## Development of Additives and Coatings to Enhance SEI Stability Beyond Fluoroethylene Carbonate (FEC)

- Initiated electrolyte additive study with silane-based molecules
- Began surface treatment of the silicon particles with silane coupling agents
- Initiated screening of SEI additives with flexible linkage and cross-linking groups
  - Long linkages are expected to afford flexibility of the SEI layers
  - Cross-linking groups including epoxy, vinyl, etc, will help to improve the mechanical property of SEI layers

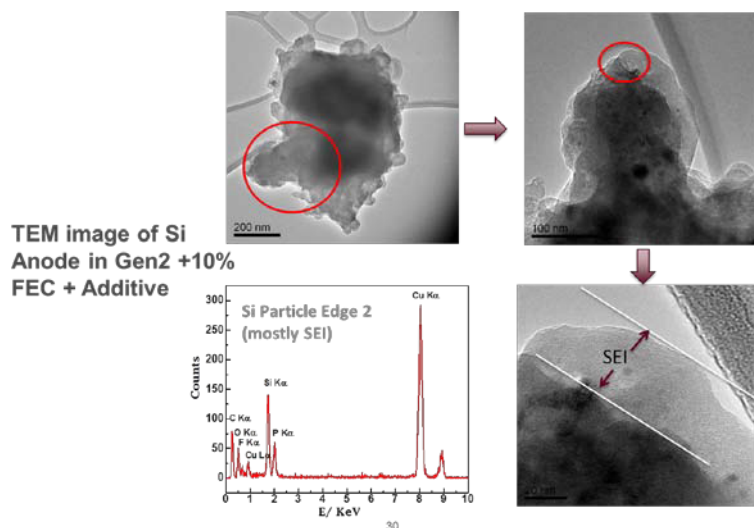

## IMPACT OF ADDITIVE ON SILICON ANODE

## Evolution of SEI Interfacial Impedance During Early Cycling Used as an Indicator of SEI Stability

**Electrode:** Si: Super P: PAA = 2:1:1

**Electrolytes:** Gen 2 (EC:EMC); Gen 2+10% FEC;  
Gen2+ 10% FEC+ 0.5% Hexamethyldisilazane

# FUTURE WORK

## Future Efforts Focused on Building and Expanding Early Diagnostic and Materials Development Studies

- Explore and study range of available silicon materials to establish new baseline.
- Expand electrochemical and analytical diagnostic studies. Sample highlights:
  - *In-situ* and *ex-situ* micro-Raman imaging
  - EQCM-D to identify surface film properties
  - Soft x-ray microscopy and Nanotomography.
- Further evaluation of safety and abuse tolerance, focusing on determining correlation between material level and full cell level.
- Continue materials development efforts, testing promising candidates in full cells, including:
  - Optimize  $\text{Li}_5\text{FeO}_4$  as a cathode lithium inventory additive and explore alternative methods.
  - Extend studies on amorphous  $\text{Si}_{0.64}\text{Sn}_{0.36}$
  - Synthesize and examine a range of functional binders.
  - Further explore surface modification studies using molecular and atomic layer deposition, silane-based particle coatings, and electrolyte additives

# SUMMARY

## Efforts Focused on Standing Up the Program and Initiating an Extensive Array of Diagnostic and Materials Development Studies

- Adopted electrodes and protocols from CAMP facility for initial baselines.
- Initiated integrated electrochemical and analytical diagnostic studies. Sample highlights:
  - Reference electrode studies
  - NMR spectroscopy investigations
  - Studies on model systems
- Began evaluation of safety and abuse tolerance.
- Initiated materials development efforts. Highlights include:
  - Synthesized  $\text{Li}_5\text{FeO}_4$  as a cathode additive for a lithium inventory source.
  - Started studies on amorphous  $\text{Si}_{0.64}\text{Sn}_{0.36}$
  - Synthesized a number of functional binders and began evaluation.
  - Began surface modification studies using molecular and atomic layer deposition, silane-based particle coatings, and electrolyte additives
